

$$8(0) = K \int_{-\infty}^{+\infty} |G_{TC}(t)|^2 dt = 1 \longrightarrow K = 1$$

$$1 \quad \text{I regals e } T \cos radiate \text{ home energie} = 1$$

$$3) \quad 8_{R}(t) = 8_{T}(t)$$

2. So calado la P(e) se il decisore utilizza una seglia $\lambda = -1$

con
$$\sigma_{n}^{2} = \frac{N_{o}}{2} \int_{-4/T}^{4/T} |G_{R}(f)|^{2} df = \frac{N_{o}}{2}$$

$$P(e) = P(1) P(e|1) + P(-1) P(e|-1)$$

$$\mathbb{P}(e \mid -L) = \mathbb{Q}\left(\frac{\lambda - M_{2|\bullet|}}{\sigma_n}\right) = \mathbb{Q}\left(\frac{-1+L}{\sigma_n}\right) = \frac{L}{2}$$

$$P(2|1) = Q\left(\frac{M_{2|1}-\lambda}{\sigma_m}\right) = Q\left(\frac{2}{\sigma_m}\right)$$

$$\Rightarrow P(e) = \frac{1}{4} + \frac{1}{2} Q\left(\frac{2}{\sigma_n}\right) = \frac{1}{4} + \frac{1}{2} Q\left(\frac{8}{N_o}\right)$$
